In order to continue enjoying our site, we ask that you confirm your identity as a human. Thank you very much for your cooperation. Figure 1 Clinical study procedure. Figure 1 Clinical study procedure. by Maïke Rahn, PhD An important question that the consultants at The Analysis Factor are frequently asked is: What is the difference between a confirmatory and an exploratory factor analysis? A confirmatory factor analysis assumes that you enter the factor analysis with a firm idea about the number of factors you will encounter, and about which variables will most likely load onto each factor. Your expectations are usually based on published findings of a factor analysis. An example is a fatigue scale that has previously been validated. You would like to make sure that the variables in your sample load onto the factors the same way they did in the original research. In other words, you have very clear expectations about what you will find in your own sample. This means that you know the number of factors that you will encounter and which variables will load onto the factors. The criteria for variable inclusion are much more stringent in a confirmatory factor analysis than in an exploratory factor analysis. A rule of thumb is that variables that have factor loadings > 0.5 , the correct a priori model specification, and data must come from a random sample. Key Terms: Theory: A systematic set of causal relationships that provide the comprehensive explanation of a phenomenon. Model: A specified set of dependent relationships that can be used to test the theory. Path analysis: Used to test structural equations. Path diagram: Shows the graphical representation of cause and effect relationships of the theory. Endogenous variable: The resulting variables that are a causal relationship. Exogenous variable: The predictor variables. Confirmatory analysis: Used to test the pre-specified relationship. Cronbach's alpha: Used to measure the reliability of two or more construct indicators. Identification: Used to test whether or not there are a sufficient number of equations to solve the unknown coefficient. Identifications are of three types: (1) under-identified, (2) exact identified, and (3) over-identified. Goodness of fit: The degree to which the observed input matrix is predicted by the estimated model. Latent variables: Variables that are inferred, not directly observed, from other variables that are observed. Confirmatory factor analysis (CFA) and statistical software: Usually, statistical software like AMOS, LISREL, EQS and SAS are used for confirmatory factor analysis. In AMOS, visual paths are manually drawn on the graphic window and analysis is performed. In LISREL, confirmatory factor analysis can be performed graphically as well as from the menu. In SAS, confirmatory factor analysis can be performed by using the programming languages.
